Process Monitoring detects and records processes and service activity, providing alerts on important behavior such as hosts running black-listed processes (peer-to-peer clients), critical processes stopping or non-approved processes starting.

Network Monitoring provides a detailed log of all network connections opened and closed on a host. It identifies and alarms on critical events such as unauthorized web or FTP servers.

Data Loss Monitoring prevents data movement to/from removable media such as CD/DVD-RW devices and USB drives. This component logs, alerts on and audits all movement of data to removable media ports and can block data transfers on selected machines and devices.

User Activity Monitoring logs any user or process that authenticates or attempts to authenticate to a host, thus identifying unexpected behavior and providing alerts on such threats as brute force attacks or unauthorized account creation or privilege modification, also providing audit trail capabilities of these uses and behaviors.

Windows Registry Monitoring sees changes to the Windows Registry and triggers alarms. If the change is determined to be malicious, administrators can approve automatically disabling the startup processes to prevent the spread of malware.
